
PUBLIC SURVEY STATUS REPORT (103rd OPC MEETING)

This report should be returned to the Observing Programmes Office of the European Southern Observatory (opo@eso.org) by Oct. 30, 2018. This report will be reviewed by the EST, OPC and Public Survey Panel.

PROPOSAL ESO No.: 177.A-3011

TITLE: VST ATLAS

PRINCIPAL INVESTIGATOR: T. Shanks

1. Scientific Aims (brief description)

The main aim of the VST ATLAS is to make a survey of $\sim 4700\text{deg}^2$ in the Southern Hemisphere in the *ugriz* bands to the depth of SDSS. The ATLAS covers $\sim 2200\text{deg}^2$ in the North Galactic Cap between $10\text{h} < \text{RA} < 15\text{h}30$ and $\sim 2500\text{deg}^2$ in the South Galactic Cap between $21\text{h}30 < \text{RA} < 04\text{h}00$. The main motivation for the survey is for cosmology. For example, there is the possibility of using the VST ATLAS UV coverage as the base for spectroscopic QSO redshift surveys out to $z=2.2$ in order to use QSO clustering to investigate primordial non-Gaussianity, the power-spectrum turnover and BAO measurements of the Dark Energy equation of state at $z\sim 1.5$. 17 nights of pilot survey observations based on ATLAS data have already been carried out on the AAT 2-degree Field (2dF) facility and future AGN surveys from e-ROSITA and 4MOST will greatly benefit from these data. This quasar redshift survey has further demonstrated the power of combining ATLAS with WISE satellite data in the L(3.4micron) and M(4.6 micron) bands to increase the quasar sky density. ATLAS data can also be further combined with the VISTA Hemisphere Survey to produce *ugrizYJKLM* photo-*z* for galaxies out to $z\sim 1$. Then cross-correlation of Luminous Red Galaxies with CMB fluctuations will test the evidence for an accelerating Universe via the Integrated Sachs Wolfe effect. Many other non-cosmological projects are clearly also feasible including the search for high redshift $z>6$ QSOs via optical dropout, the search for stellar streams and the search for local large scale structure including the Great Attractor. Indeed, our aim is that ATLAS becomes the equivalent of a Southern Sloan with similar scientific impact. ATLAS Data Release 4 (DR4) covering the period from 1/8/2011 - 30/6/2017 will soon be available from the ESO archive.

The ATLAS area originally approved by the PSP is now complete. However, it was always envisaged that ATLAS would cover $\sim 4700\text{deg}^2$ by including the area at $b>29\text{deg}$ and $\text{Dec}<-20$ in the NGC and the science case in the revised Survey Management Plan assumed this increased area. At its April 2014 meeting, the PSP gave approval to observe this extra area in the *iz* bands to take ATLAS to its full 4700deg^2 area. Chilean VST proposals (PI L Infante) were accepted by ESO in P95 +P96 to survey this extended area in the *ugr* bands. However, progress was slow and in P101 and P102, $2\times 78\text{hrs}$ of public survey time was allocated to complete *ugr* in this 745deg^2 area. Only $\sim 27\text{h}$ of time was used in P101 and none so far in P102. Assuming a similar final outcome in P102 as in P101, we request a further $2\times 50\text{h}$ of VST dark time in P103 and P104 to complete the survey.

2. Detailed progress report with respect to initial estimate from the Survey Management Plan.

2.1 Scientific Progress and Outlook

The VST ATLAS now has covered the equivalent of $\sim 4000 \text{ deg}^2$ in *ugr* and $\sim 4740 \text{ deg}^2$ in *iz* between mid-August 2011 and June 2017 in Periods 87 - 99 (see status maps at <http://astro.dur.ac.uk/Cosmology/vstatlas/>). Apart from a handful of tiles being re-observed, all *ugr* tiles in the original ATLAS area of 4000 deg^2 and all *iz* tiles in the full ATLAS area of $\sim 4700 \text{ deg}^2$ have been completed. Still to be completed is the NGC ATLAS “extension” at $\text{Dec} < -20$ in *ugr*. It is already complete in *iz*. The extra NGC area in *ugr* corresponds to 797 tiles. Table 1 shows how many of these were completed since 1/10/17 by passband.

Band	Completed	Failed	Scheduled
U	47 (47)	11	707
G	208 (153)	0	560
R	290 (255)	0	458

Table 1. Total number of VST ATLAS NGC $\text{Dec} < -20 \text{ deg}$ pointings completed up to October 2018. Scheduled means OB submitted. Number in brackets in the Completed column shows tiles completed in the last year.

As noted above, PSP at its 28-29/4/14 meeting recommended that we be allowed to extend the survey to its originally envisaged $\sim 4700 \text{ deg}^2$ by allowing us to survey the NGC area above galactic latitude $b > 29$ and $\text{Dec} < -20$ in *iz*. Chilean proposals (PI L. Infante) to complete the survey of this extended area in *ugr* were accepted by the ESO TAC for P95 (095A-0561) and P96 (096.A-0921) but only 28 (*u*), 35 (*g*) and 55 (*r*) tiles out of 797 in each band were completed, with the *u* data in particular being taken in too poor seeing to be useful (see Section 4 below). To cover the full area would take 69h (*u*), 45h (*g*) and 42h (*r*) of VST time. In our report a year ago we made the case that this total of 156h of time should be completed as a public survey and this was approved by the OPC.

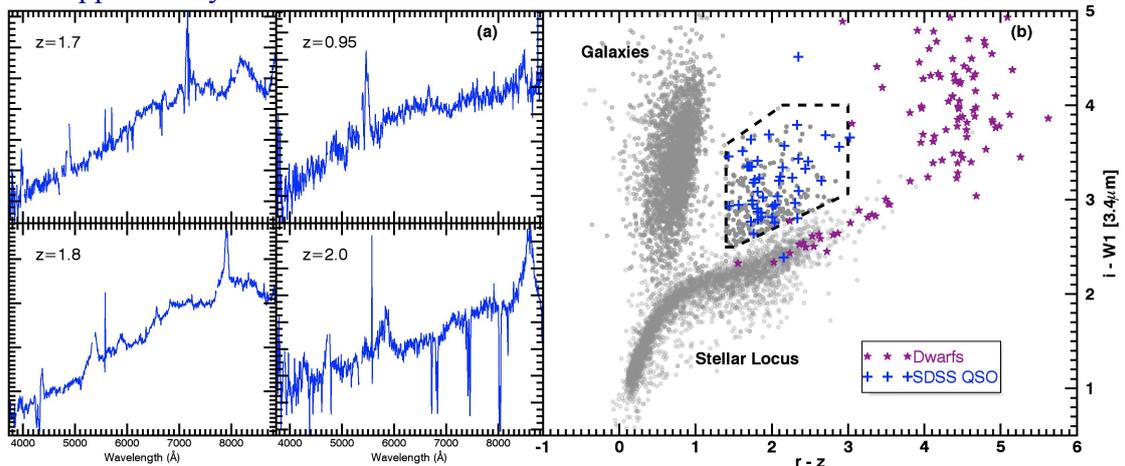

Fig. 1a. 4 examples of a new population of dust absorbed red quasars at $z < 2.5$ selected from *g-i-i-W1* by a combination of WISE and ATLAS. Spectra from AAT 2dF AAOmega (Chehade et al 2016). **Fig. 1b.** WISE and ATLAS *r-z:i-W1* colour-colour plot shows high efficiency in isolating previously discovered SDSS $5 < z < 6$ quasars.

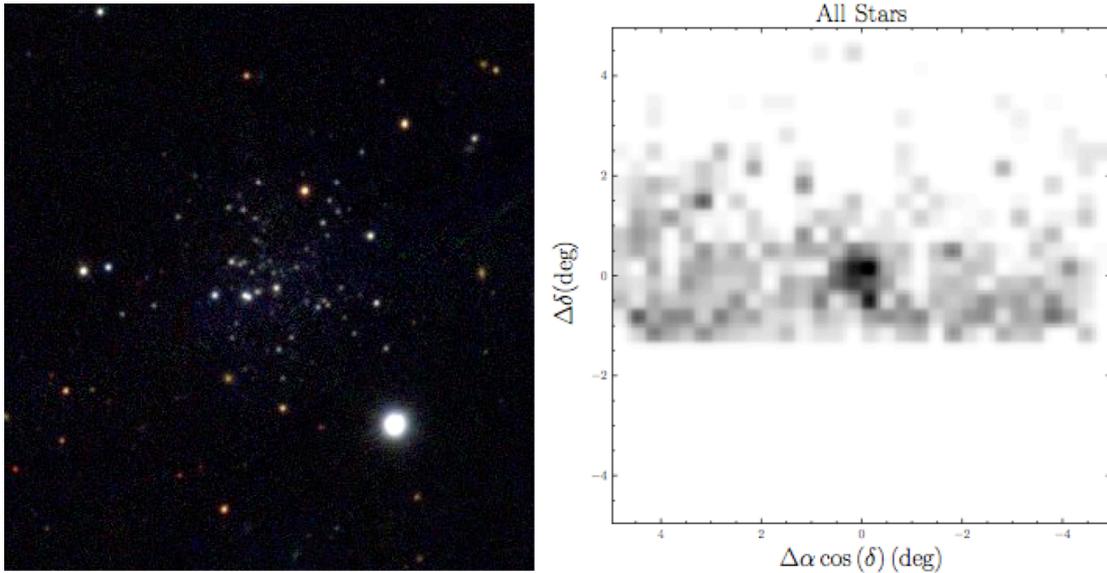

Fig. 2a Discovery of the Crater Milky Way satellite in VST ATLAS survey data as shown here in a $\sim 3 \times 3$ arcmin true colour gri image (Belokurov et al, 2014). **Fig. 2b** The Crater 2 satellite galaxy is similar in size to LMC but with a very low velocity dispersion (Torrealba et al, 2016).

As examples of science highlights, in Fig 1a we show results from the 2QDES pilot survey where 10000 $0.5 < z < 3.5$ quasar redshifts were observed using the combination of ATLAS and WISE photometry (Chehade et al 2016). A population of obscured dusty quasars were also found, some examples of whose very red spectra are shown here. In Fig 1b a redder combination of ATLAS and WISE bands is used to select higher redshift $5 < z < 6$ quasars and follow-up of these candidates is ongoing.

Another science highlight is that ATLAS is also proving ideal for searching for Milky Way satellites as shown by the discovery by Belokurov et al (2014) of the Crater dwarf galaxy, a new Milky Way satellite (see Fig. 2a) and the Crater 2 dwarf by Torrealba et al (2016, see Fig. 2b). Koposov et al (2014) have also found a new stellar stream using ATLAS data.

A further science highlight is the discovery of four $z > 6$ quasars by combining ATLAS and WISE photometry (Carnall et al 2015, Chehade et al 2018). The quasars' VLT X-shooter spectra are shown in Fig. 3 were initially confirmed by observations using Magellan LDSS-3 (top 2), Keck LRIS and NTT EFOSC2.

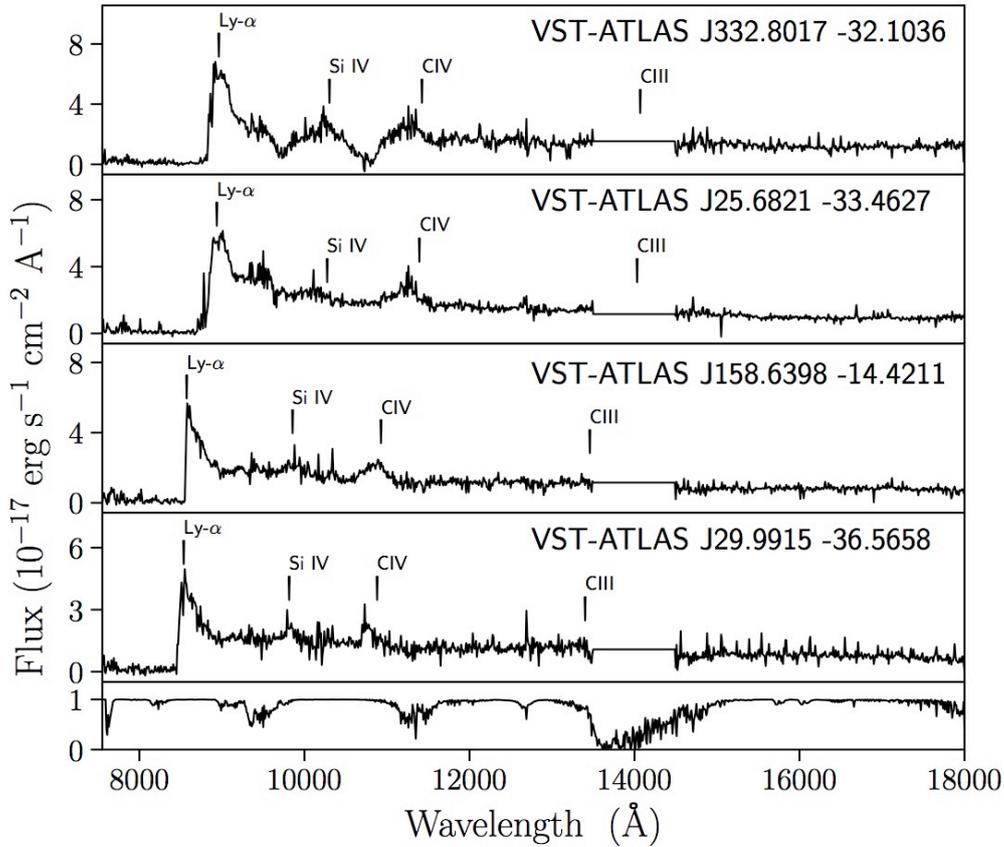

Fig. 3 Four $z > 6$ quasars spectroscopically confirmed at Magellan(x2), Keck and NTT. The discovery of these quasars is described by Carnall et al (2015) and Chehade et al (2018). Here, their VLT X-shooter spectra are shown plus the atmospheric transmission in the lowest panel.

We note that the GAMA, OzDES and 2dFLENS collaborations are also using imaging data from VST ATLAS. The 2dF galaxy redshift survey of the Cold Spot void (Mackenzie et al 2017) is also based on VST ATLAS imaging data.

The excellent seeing and wide area of VST ATLAS can be exploited by studies of galaxy-galaxy lensing. SDSS claimed significant results in this area and ATLAS seeing is some 50% better than theirs. The Bonn group (D Klaes et al) is re-reducing the ATLAS data for such lensing purposes.

The excellent seeing also means that ATLAS (+WISE) data can be used to detect “quad” gravitational lenses like those whose HST images are shown in Fig. 4 (Schechter et al 2017).

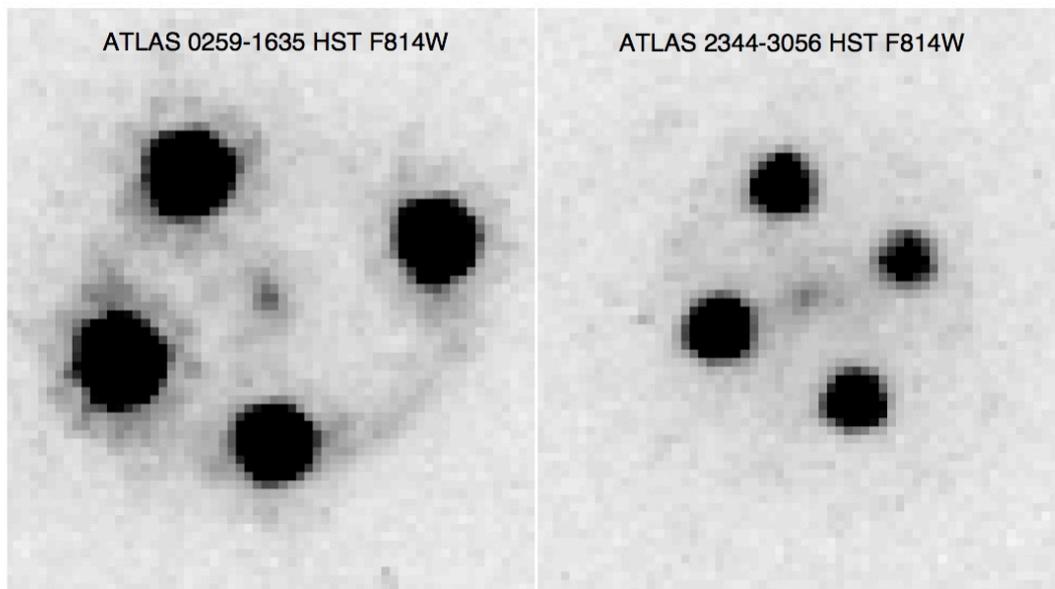

Fig. 4 HST WFC3 images of two quad lensed quasars found from analysis of WISE and ATLAS data (Schechter et al 2017).

We have also published online the presentations of the 3-day workshop "Exploiting the VST ATLAS... and its sister surveys" held at Durham University on 14-16 April, 2014. (see <http://astro.dur.ac.uk/VSTWorkshop/programme.php>)

2.4 Overall survey status: where does the survey stand scientifically compared to other survey projects, either ongoing or to be started in the near future?

VST ATLAS main competitors are PanSTARRS, DES and DECaLS. None of these surveys observe in the u band so ATLAS is unique in this respect. None of these surveys have or will have as good seeing as VST ATLAS (Shanks 2015) so ATLAS is also unique in this respect. The combination of excellent seeing and UV sensitivity means that ATLAS is ideal for UVX quasar surveys. This is particularly the case if the Chilean u extension is included which means, in the combined survey (4x60s in u), we can reach quasars down to a limit of $g=22.5$ where the sky density is $\sim 130 \text{ deg}^{-2}$. We are therefore currently exploring the possibility of complementing the eROSITA X-ray AGN survey with 4MOST spectroscopic follow-up using ATLAS

optical identifications. T Shanks is now an eROSITA external collaborator to promote eROSITA–ATLAS collaboration. In P100-P103 we applied for DEUCE (PI T Shanks), a further ATLAS u extension as a VST “filler” programme to cover 2800 deg² of the DES survey area to support eROSITA AGN follow-up.

2.5 About survey completion: what has been achieved? How much of the survey has been completed?

All of the original ATLAS OBs have now been observed covering $\sim 4000\text{deg}^2$ in ugr and $\sim 4700\text{deg}^2$ in iz . What remains is the ugr extension in the NGC at Dec<-20deg. Table 2 shows how the ATLAS NGC Dec<-20deg extension OBs have been completed in P101 and to date in P102.

Public survey of NGC area at Dec<-20 in ugr . As noted in Section 2.1 the NGC area at Dec<-20deg although complete in iz , is still to be completed in ugr (see Figs. 5(u), 6(g), 7(r)). The original plan was that this area be done in Chilean time with PI L. Infante. But in P95+P96 (095A-0561 and 096.A-0921) only $\sim 8\text{h}$ out of 160h allocated was observed. In subsequent periods we therefore focused on completing the doubling of the ATLAS u exposure in the original 4000deg^2 ATLAS ugr area. This latter project is still ongoing. To speed progress, a year ago the OPC therefore re-instated the NGC Dec<-20 ugr survey as a public survey, as was originally envisaged. The motivation to complete the optical survey remains high given particularly the uniqueness of the ATLAS u coverage, combined with ATLAS excellent seeing, especially advantageous for point sources such as quasars. This makes ATLAS u a natural complement to the follow-up of the eROSITA-DE X-ray AGN survey and the targeting of the 4MOST quasar cosmology survey. Clearly it is most efficient in terms of telescope time to maintain the $2\times 120\text{s}$ u band exposures over this area, which is the combined u exposure from the ATLAS+Chilean u surveys over the 4000deg^2 area. We would also maintain the $2\times 50\text{s}$ g -band and $2\times 45\text{s}$ r -band exposures, consistent with the rest of ATLAS. The usual ATLAS seeing and airmass constraints would still be applied. Including overheads, we requested 156 h of VST dark time for this purpose. The survey will be ready early enough for eROSITA and 4MOST in 2022 if completed over the next few periods. Table 2 summarises the progress in P101 and P102 with 27h observed in P101. We therefore request 50h in each of P103 and P104 to complete ugr in the NGC at Dec<-20deg. We require seeing of 1.4 arcsec FWHM in u and airmass<1.4 as usual.

Band	P101 (P)			P102 (R)		
	√	X	?	√	X	?
u	47	11	313	0	0	398
g	153	0	217	0	0	343
r	255	0	115	0	0	343

Table 2. VST ATLAS NGC extension at Dec<-20deg pointings summarised by Period and bandpass. √ means completed, X means failed/rescheduled and ? means OB submitted but not completed.

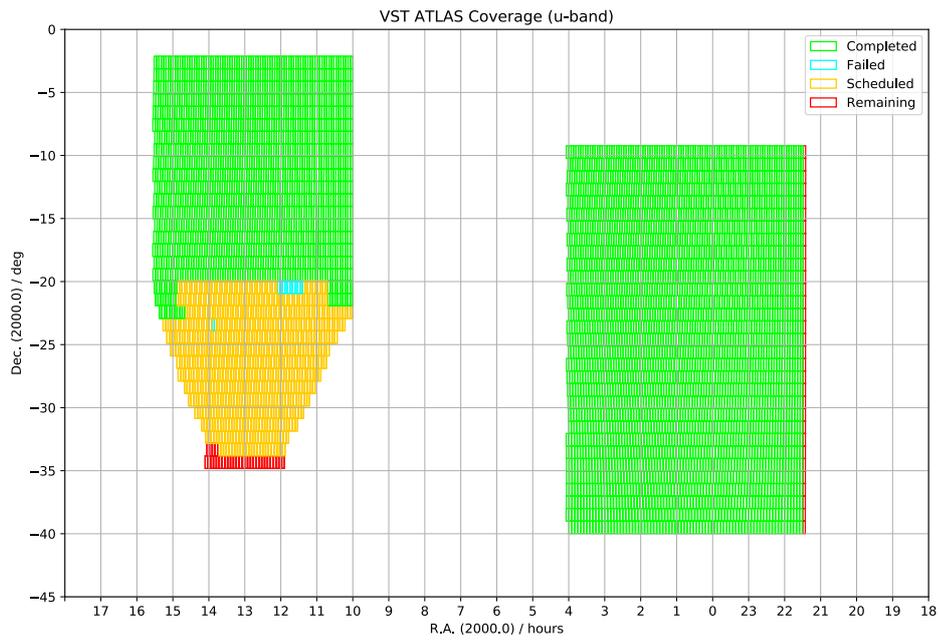

Fig. 5. The ATLAS survey areas marked in green are completed in u. The NGC area below $Dec < -20deg$ is currently progressing as an extension, although it is already complete in iz.

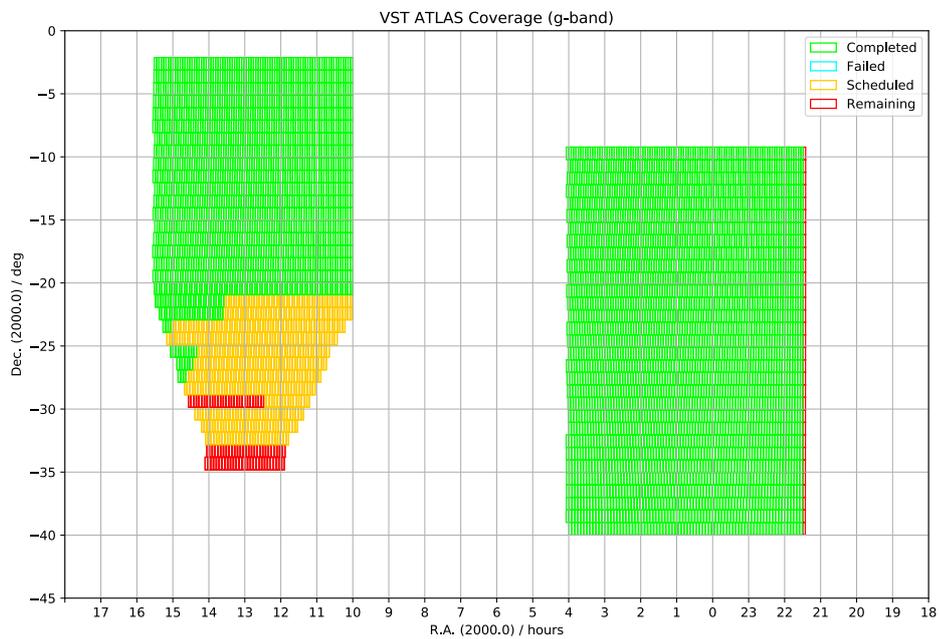

Fig. 6. The ATLAS survey areas marked in green are completed in g. The NGC area below $Dec < -20deg$ is currently progressing as an extension, although it is already complete in iz.

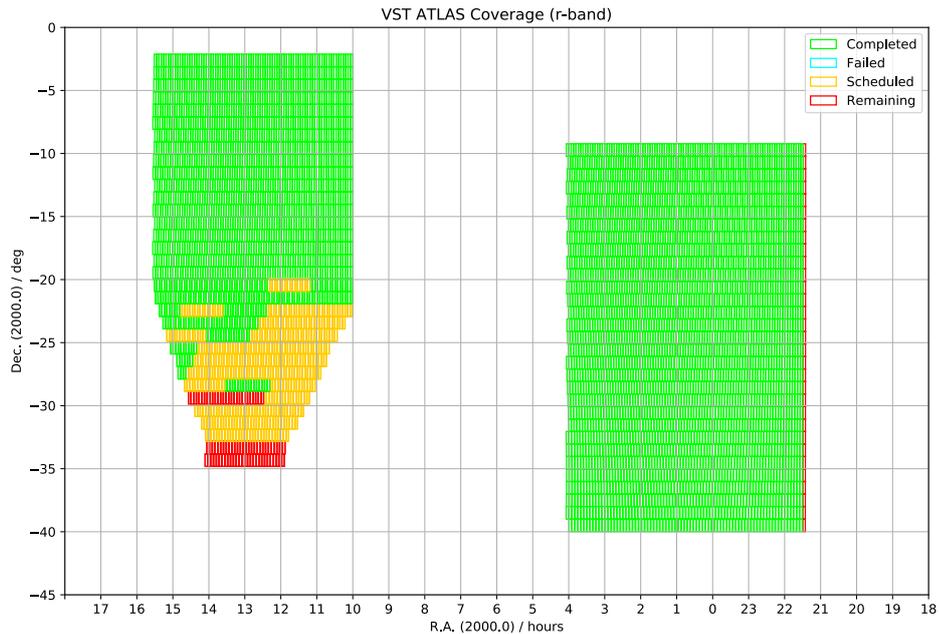

Fig. 7. The ATLAS survey areas marked in green are completed in r. The NGC area below $Dec < -20deg$ is currently progressing as an extension, although it is already complete in iz.

3. Quality Control and Phase 3. The Phase 3 submission plan should be described here.

3.1 The PI should comment on the quality control and the science validation of the acquired data.

Quality control is ongoing at Cambridge, Durham and Edinburgh. Generally data quality is excellent. The most important way to validate the data is by using it for science projects and we originally carried out 17 nights of pilot observations for a proposed AAT 2dF quasar redshift survey called the 2dF QSO Dark Energy Survey (2QDES). VST ATLAS provided the imaging data base for these pilot observations between December 2011 and July 2013. We prepared ~ 200 sq deg of ATLAS imaging data using $u-g:g-r$ and $g-r:r-i$ colour-colour diagrams to select QSO candidates which were then observed ~ 330 at a time using 2dF. The observations realized ~ 10000 QSO redshifts. 2dF fibre observations are clearly quite demanding, even more so since we were pushing to a limit of $g \sim 22.5$ for QSO identifications. The success of the observations confirm that the positions for faint stellar objects are good enough for them to be observed in 2.1 arcsecond diameter fibres over a 3 sq deg field simultaneously. It also confirms that the CASU photometry reaches the equivalent of $g \sim 22$ in the u -band. The best rates we have achieved from ATLAS are QSO sky densities of 95 deg^{-2} or about 300 per 2dF field (Chehade et al 2016). This is even before the inclusion of the ongoing Chilean u band extension (PI L. Infante) which doubles the u band exposure to 240s.

CASU have implemented an illumination correction that reduces centre to edge photometric offsets from $\sim 0.25\text{mag}$ to $\sim 0.01\text{mag}$. This is now within the tolerance needed for projected galaxy and quasar clustering analyses.

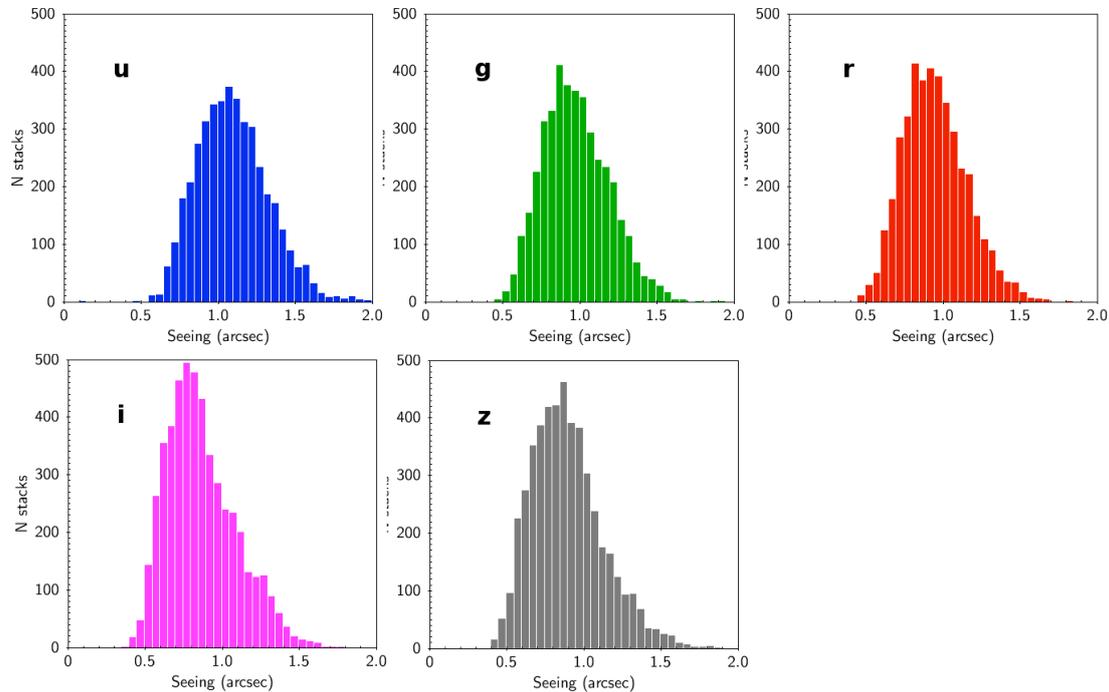

Fig. 8. Seeing (FWHM) distributions from ATLAS A, B grade stacks.

We also note that the ATLAS median seeings (see Fig. 8) in the *riz* bands are 0.90, 0.81 and 0.84 arcsec FWHM. In *u* and *g* the median seeings are 1.0 and 0.95 arcsec FWHM. These distributions are well within our $<1.4\text{arcsec}$ specification and are significantly better than the SDSS equivalents. ATLAS median 5σ stellar AB magnitude limits are 22.0 in *u*, 23.1 in *g*, 22.67 in *r*, 22.0 in *i* and 20.87 in *z*, again well within specification. Full details of these and other survey characteristics are given in our DR3 release descriptions that accompany the data on the ESO SAF (or see <http://astro.dur.ac.uk/Cosmology/vstatlas>).

Until now we have calibrated magnitude zeropoints using APASS star magnitudes and these still show problems due to the need to extrapolate to *u* and *z* from APASS *gri* and due to some residual issues in the APASS *gri* photometry. With the completion of ATLAS, we are now in a better position to use the 2 arcmin overlaps between tiles to produce an improved calibration, particularly in *u*, because this method requires large contiguous areas. We are also using the Gai DR2 G , B_p and R_p photometry to finalise our global photometry scales in *griz*.

3.2 The PI should describe here the current status of the Phase 3 submission for her/his survey project and specify how s/he wishes to structure the submission of data products during the year 2019. These plans will be reviewed and iterated with ESO to reach agreement. PIs should also include any relevant information for the scientific validation of the data products.

The Phase 3 submission plan remains the one described in Section 5 of the Revised ATLAS SMP. ATLAS DR3 was released in November 2016 based on data taken in the period 1/8/11-1/10/14. DR4 now scheduled for December 2018 is envisaged to be the final release for the original ATLAS areas. DR1, DR2 and DR3 are only flux calibrated on a nightly basis, whereas DR4 will place the entire survey on a uniform photometric scale in all 5 bands.

In addition to the DR1, DR2 DR3 catalogue releases indicated above, the ATLAS team also delivers the following core data products to the ESO SAF:

- astrometrically and photometrically calibrated images, along with their respective weight maps, in all of the project-relevant filters are provided on a per pointing basis.
- source catalogues based on individual bands. Associated source catalogues linking the parameters of individual objects across all of the observed filter bands are provided on a pointing by pointing basis.
- these survey products are supported and characterized by additional “meta” information providing a full description sufficient for their full scientific exploitation.
- For DR2 and DR3 we also provided *ugriz* bandmerged catalogues sourced from WFAU. This will be continued in DR4.

Further access to the ATLAS data is available at the Cambridge Astronomical Surveys Unit database (<http://casu.ast.cam.ac.uk/surveys-projects/vst>) and at the Edinburgh Wide Field Astronomy Unit archive at <http://surveys.roe.ac.k/osa>.

Year(*)	Data volume acquired per year (since 01.10.2015)	Percentage reduced data/year (since 01.10.2015)	Percentage of data (images/source lists) submitted / year (since 01.10.2015)	Percentage of catalogs submitted / year (since 01.10.2015)
10.2015-10.2016	2.7Tb	100%	100%	100%
10.2016-10.2017	~1Tb	100%	100% (incl. DR4)	100% (incl. DR4)
10.2017-10.2018	~0.25 Tb	100%	0%	9%

(*) add any number of rows needed to describe the Survey Phase3 submission status. The time interval is only indicative.

4. The PIs of the VST public surveys are requested to review the observations that were assigned a Quality Control grade “D”. Please report what fraction of the D-classified OBs must be repeated to attain their scientific goals and include an assessment of the time required to repeat these OBs.

We have assessed the D grade OBs observed since October 2017 and only 1 needs to be re-done to satisfy our survey’s scientific goals, because the Image Quality, ellipticity or seeing was usually outside specification. We therefore request 1h to take into account the increased overhead in observing a single field.

Before *ugr* in the NGC Dec<-20deg area was accepted as a Public Survey in P101, Chilean proposals (PI L. Infante) to survey this extended area in *ugr* were originally accepted by the ESO TAC for P95 (095A-0561) and P96 (096.A-0921) with 28 (*u*), 35 (*g*) and 55 (*r*) tiles out of 797 in each band being observed. Unfortunately, closer inspection reveals that none of the *u* tile observations satisfied the 1.4 arcsec seeing criterion for the ATLAS survey. We therefore propose that these fields should be re-observed. We estimate that ~4 concatenations are in this category. We therefore ask for a further 4h of VST dark time to re-observe these tiles. The total extra time requested is therefore 5h dark time in P103 for re-observing both the D grade OB and the previous NGC Dec<-20deg Chilean *u* concatenations.

Period	Field name/ mean RA	Filter	Time (h)	Seeing	Moon	Transparency
103	10h-15h30	u	5	<1."4	Dark	THN
